

Rapid VM Deployment

You have the ability to duplicate an existing VM, a process that uses clones or templates, also known as master images, golden copies, they all mean the same thing you take an existing VM and copied it. In the section I will discuss an number of methods for duplicating a VM. There are two new features in the VM duplicating world

- Hot cloning a VM
- Open Virtual Machine Format (OVF)

There are a number of ways to duplicate a VM

Clone to Template	This method copies the VM and converts it to a template format., during the creation of the template you have the ability to compact the files, which will reduce the size of the virtual disk.
Convert to Template	This simply marks the VM as a template, it's much quicker than using Clone to Template as no copy process is generated, it literally takes seconds to mark it as a template and seconds to convert it back to being a VM. You first build the VM, then convert it to a template. When you need to update this template to convert back to a VM make the updates and then convert back to a template again. You use this VM as a template only and only gets powered on when you need to update it, so basically it is like a source for creating new VM's.
Clone Virtual Machine	This merely copies a VM, you cannot compress the size of the VM (unlike Clone to Template) and you cannot quickly update the base VM (unlike convert to Template)

Before you create a Template you need to consider the below

- How big the Guest OS boot partition should be, as there is no easy way to adjust the size on the fly
- How software should you include, for example do you want to including a service pack, latest YUM updates, backup client software, antivirus software, etc

Creating a template doesn't just duplicate the VM's virtual disks, Additionally, the VM's *.vmx* configuration file is duplicated and renamed with the *.vmx* extension, this means that all the settings behind your VM are being duplicated as well. This saves time by reducing the number of wizards and dialog boxes you need to complete. Note that if a VM is currently in snapshot mode you will not be able to clone it.

I generally create a folder called "templates", from the "home page" in vCenter select "VM's and Templates", select your data center (in my case it is called production), and right-click, then select new folder and name your folder.

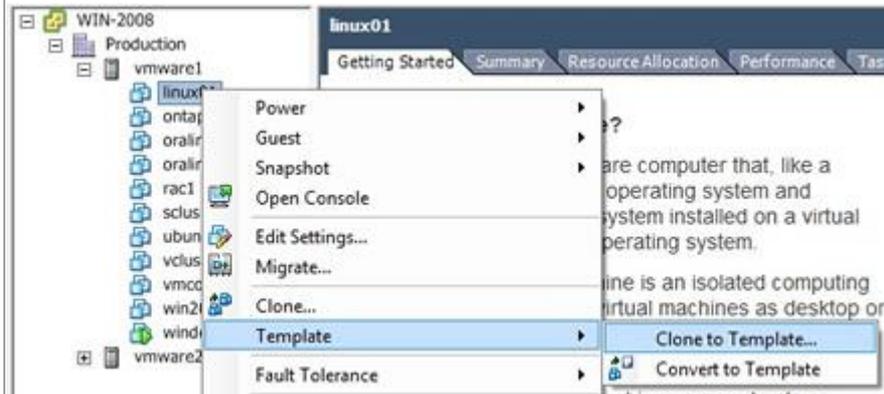

Cloning to a template

Before you clone a VM it is sometimes better to you disconnect the CDROM (you will see an error on this below) and choose a staging network that it can connect too, these can then be changed before you put the newly cloned VM into service and thus will not affect anything else.

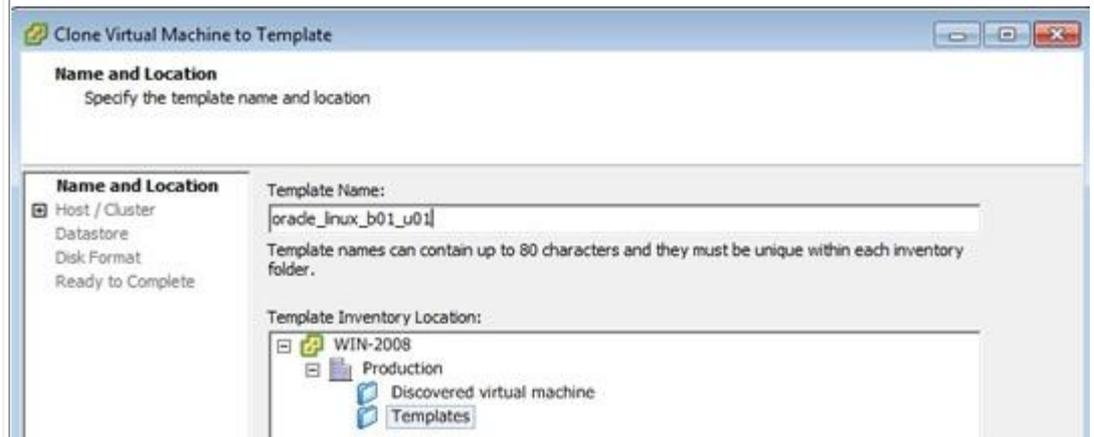

I am going to use the Linux VM we created earlier as a template, normally I would update it with the latest OS set and install any software at all Linux VM's would require, backup agent, BB monitoring (Big Brother),

Select the VM you have powered off as you source for the template, right-click the VM and select "Template" then select "Clone to Template"

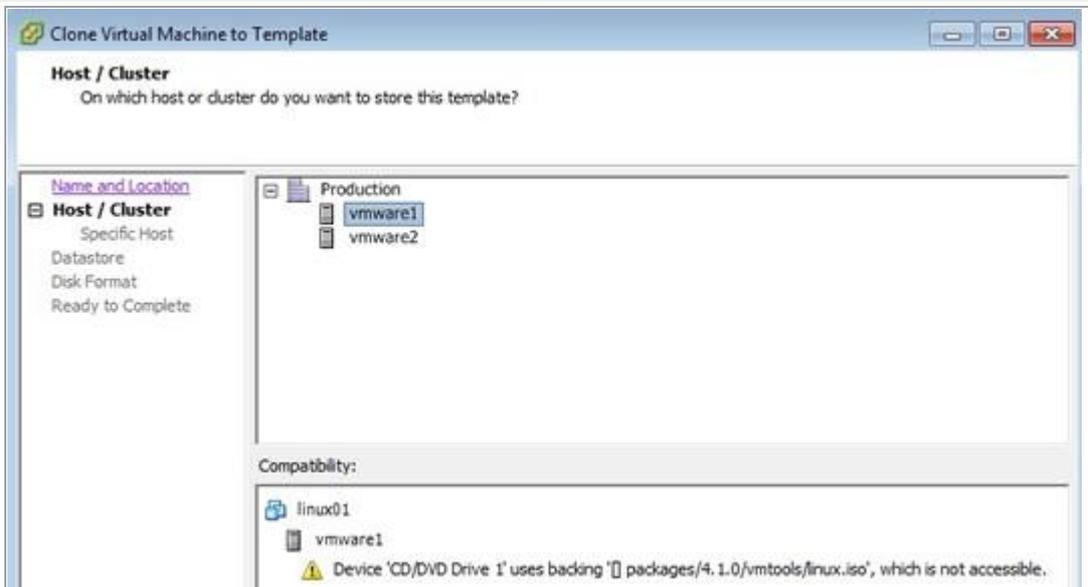

Cloning to a Template

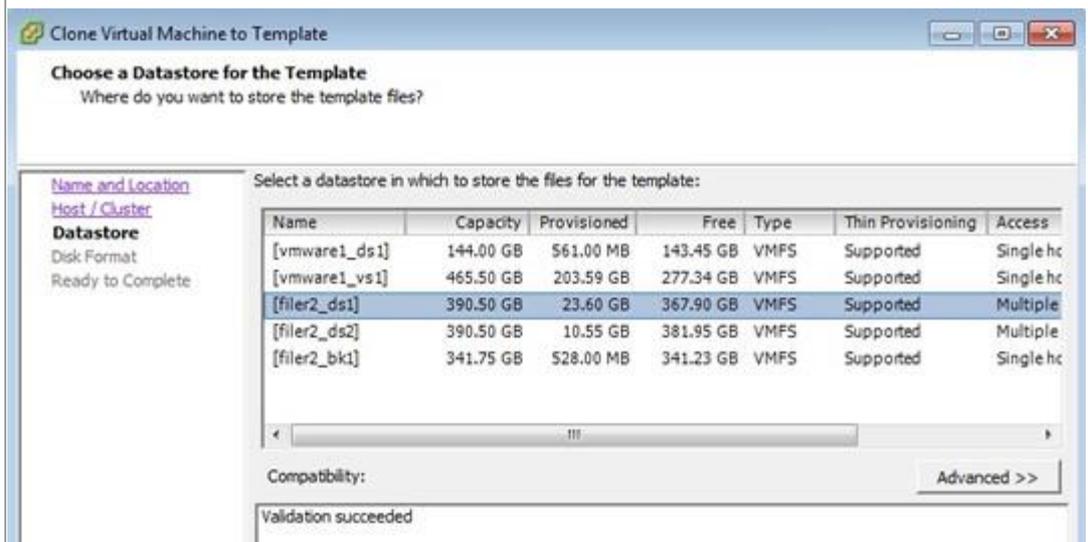

Enter a friendly name for your template, I have called mine oracle_linux_b01_u01 (b = build, u = update). I have also selected my template folder I created

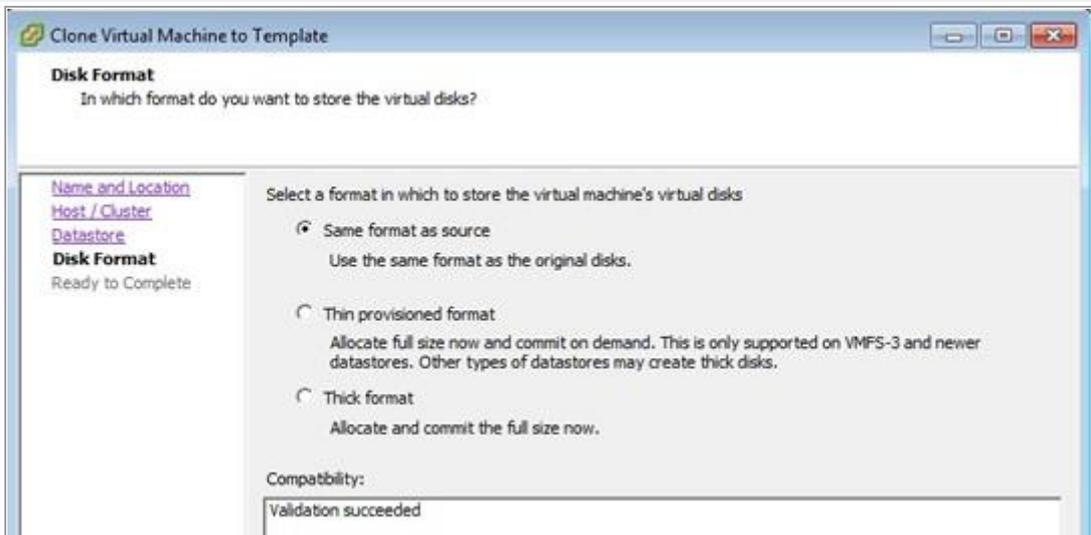

Select the Host/Cluster that you want to store the template on, at this point you may get some errors like below if the VM that you are cloning may have any problems with it, in this case I have attached a ISO in my CD/DVD drive, after I removed the attached ISO image from the CD/DVD drive it all worked

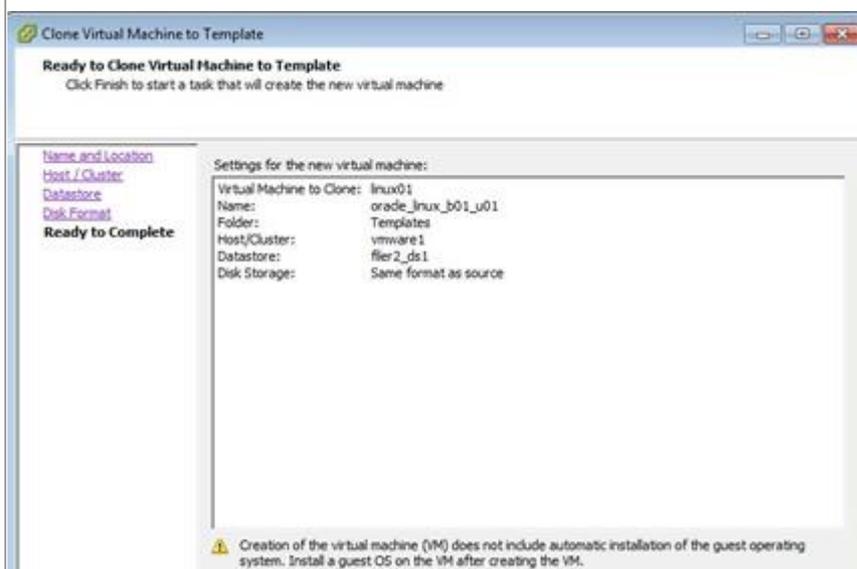

Select the physical location for storing the template files, I have put this on some shared iSCSI storage called "filer2_ds1"

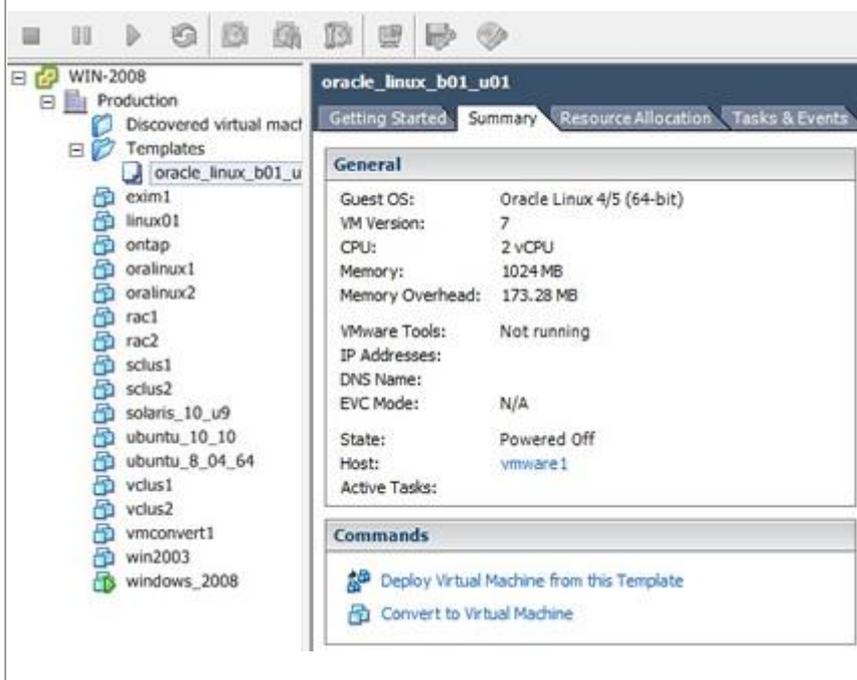

Choose the disk format, I have choose "Thin provisioned format", thus cutting down the disk required

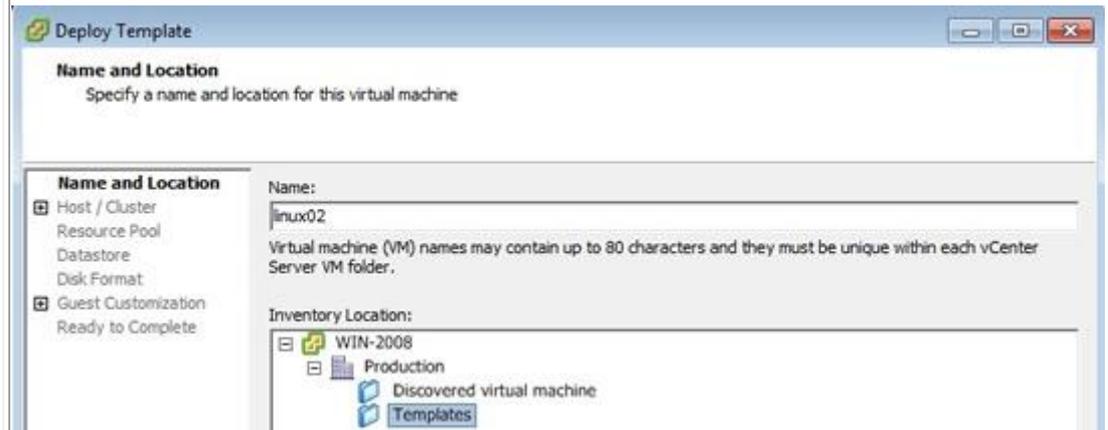

Lastly we get to the summary screen

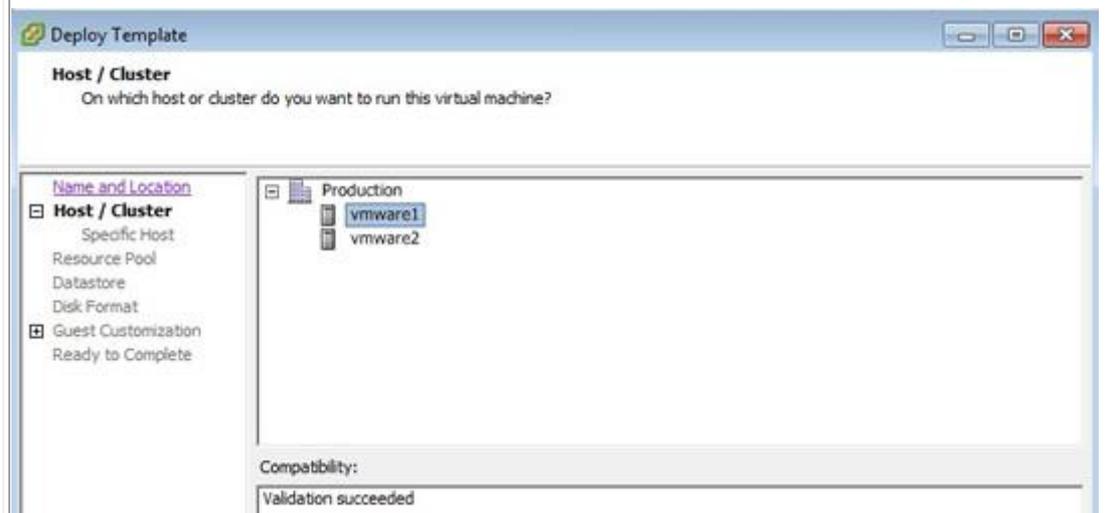

If you go to the templates and take a look at the newly created template you can see that you cannot power on this VM, you can only deploy it to a VM or convert it to a Virtual Machine. If you need to update this template you need to convert it to a virtual machine, power it on then update it, power it off, then convert it back to a template

Now that we have our cloned VM how do we use it to create other VM's, select the template VM and then select "Deploy a virtual machine from this template", then put the name of the VM and select Production

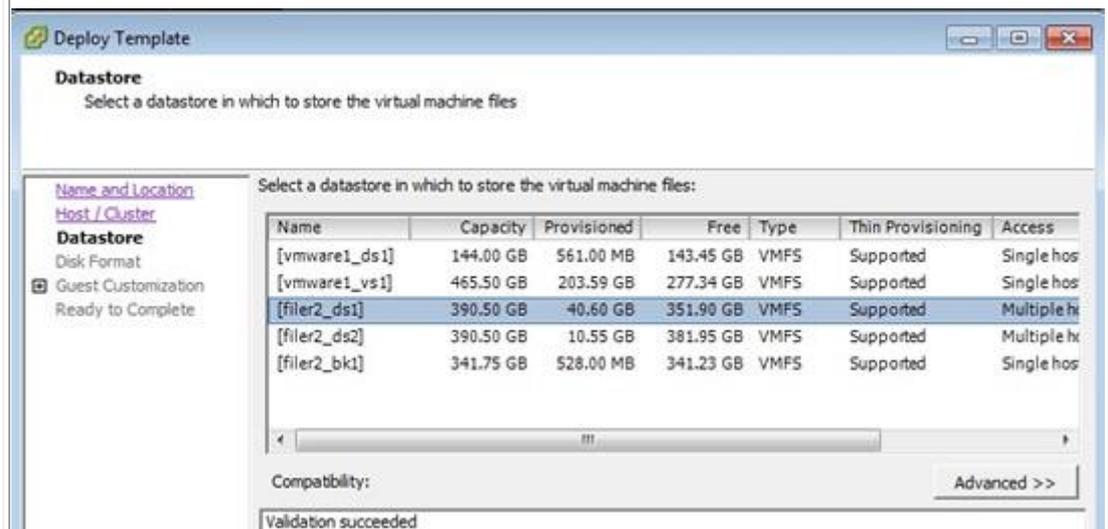

Select a ESXi server to host the VM

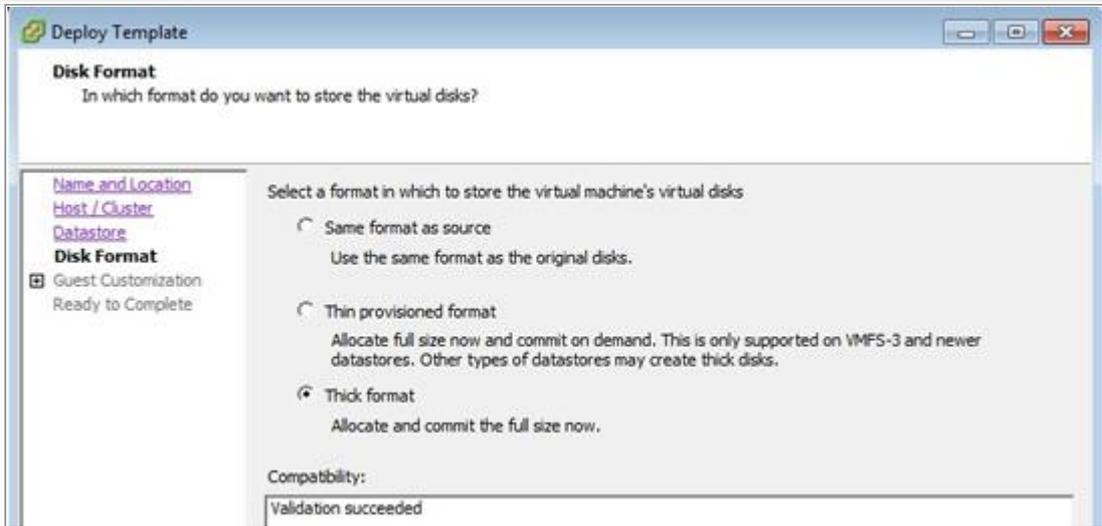

Creating a new VM from a "cloned to Template"

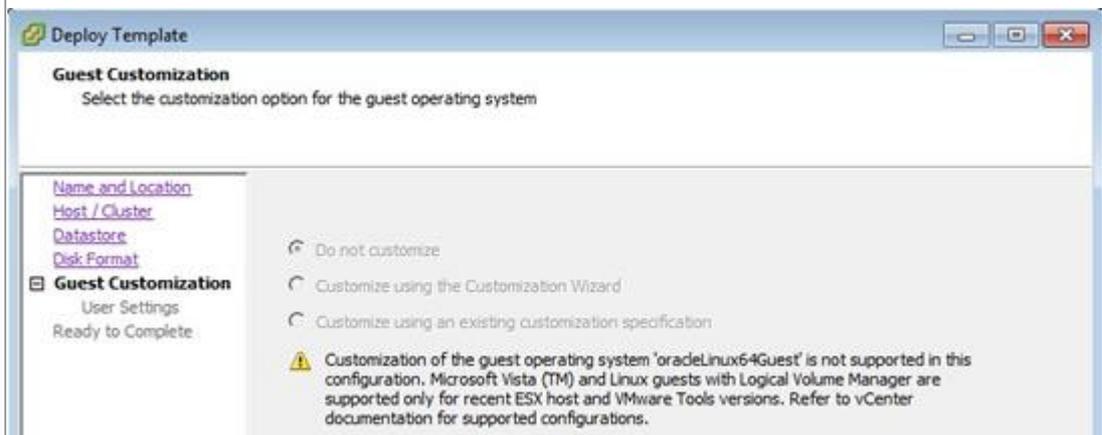

Select the datastore to store the VM

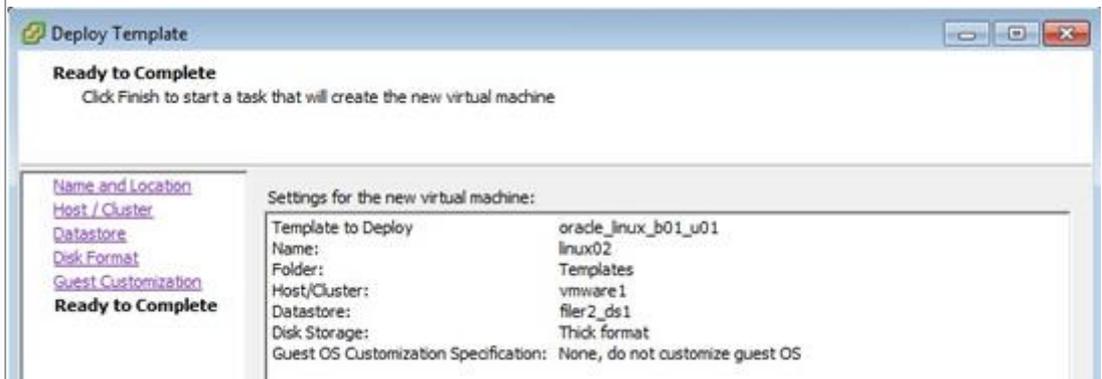

Select thick format, so that the virtual disk is fully created.

Here my vCenter does not offer customization, we will discuss this later

Finally the summary screen

Now when you look at your VM you should see the newly create linux02 VM. At this point it is just like a normal VM, you may need to change the network, CD, etc. Also when you power on the VM you may need to change the IP address, etc for your environment

The screenshot displays the VMware Workstation interface. On the left, a tree view shows the hierarchy: WIN-2008 > Production > Templates > oracle_linux_b01_u > linux02. The main panel shows the configuration for 'linux02' with tabs for 'Getting Started', 'Summary', 'Resource Allocation', and 'Performance'. The 'Summary' tab is active, showing the following details:

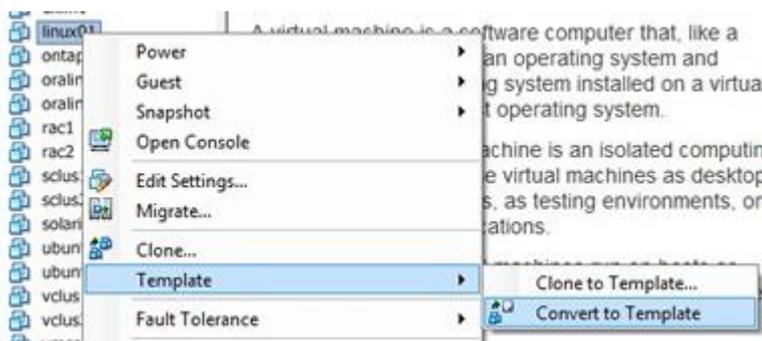

General	
Guest OS:	Oracle Linux 4/5 (64-bit)
VM Version:	7
CPU:	2 vCPU
Memory:	1024 MB
Memory Overhead:	173.28 MB
VMware Tools:	Not running
IP Addresses:	
DNS Name:	
EVC Mode:	N/A
State:	Powered Off
Host:	vmware1
Active Tasks:	

Below the general information, there is a 'Commands' section with the following options:

- Power On
- Edit Settings
- Migrate
- Clone to New Virtual Machine
- Convert to Template

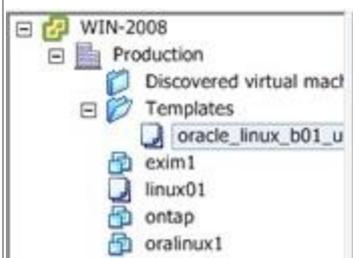

To convert a VM into a template and back into a VM follow below

Make sure that the VM is powered off, right-click and select "template", then choose "Convert to Template", the whole process should be very quick a few seconds

convert a VM to a Template and then back into a VM

You will see that that VM disappears from the list and appear in the "VM and Templates" list, you can drag and drop the linux01 template to your template area

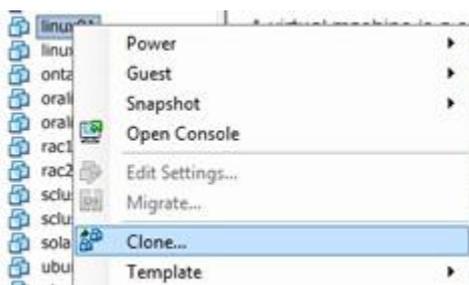

That's all there is to it, to convert back into a VM just right-click on the template select "Templates" and then select "convert into virtual machine", you will be asked a couple of easy questions (what ESXi server you want it to be deployed to).

To clone a VM just follow below

Clone a VM

Again cloning a VM is easy, just select the VM and right-click and select "clone...."

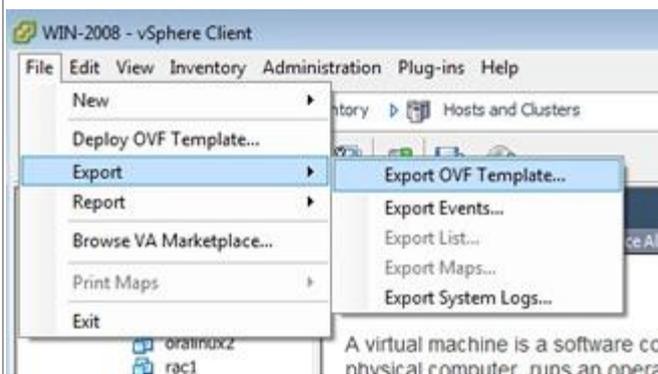

The same questions that were asked above will be asked here again, so no surprises

To export a VM to a OVF (Open Virtual Machine Format)

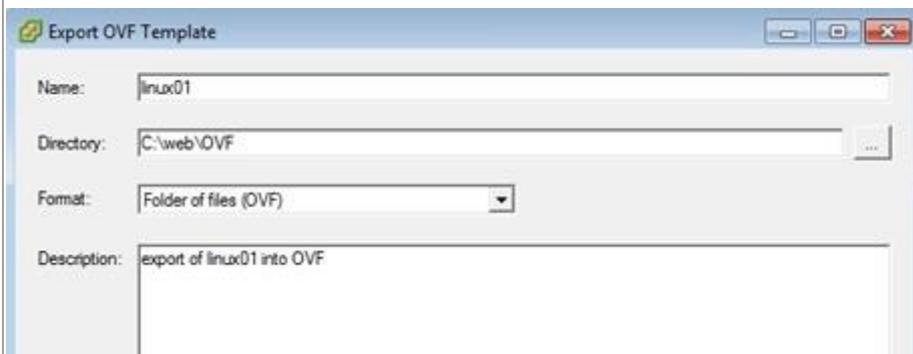

VMware's new portable format OVF, allows vendors to create a virtual machine and upload to VMware to allow others to download and import into your environment. There are no many virtual appliances in VMware [marketplace](#).

export a VM to OVF

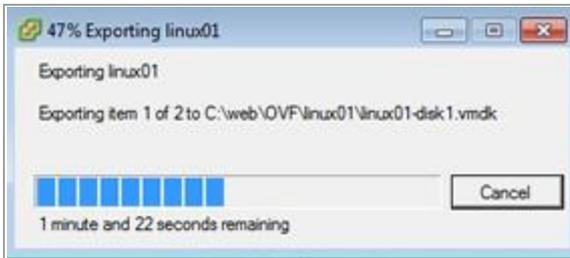

To export a VM into OVF, select the VM, then in the main vCenter window select file -> export -> "export to OVF template"

The comes a screen like below, fill in the details and select next

The export will take place, it took about 5 mins for a standard 15GB linux VM

Looking into the directory of the exported VM, you see then below

Name	Date modified	Type	Size
linux01.mf	04/04/2011 13:32	MF File	1 KB
linux01.ovf	04/04/2011 13:32	OVF File	7 KB
linux01-disk1.vmdk	04/04/2011 13:31	VMDK File	1,147,315 KB
linux01-disk2.vmdk	04/04/2011 13:32	VMDK File	71 KB
